(54) Title: CELL DERIVED ANTIGEN PRESENTING VESICLES (57) Abstract <p>The invention provides a novel vehicle for vaccination, in particular peptide vaccination. The new vehicle has been termed an exosome. Exosomes are vesicles derived from MHC class II enriched compartments in antigen presenting cells. The exosomes possess MHC II and/or MHC I molecules at their surface and possibly peptides derived from processed antigens in said MHC's. Thus the exosome is a perfect vaccination vehicle in that it presents the peptide in a natural setting. The peptides present in the exosome in the MHC molecule may be processed by the antigen presenting cell from which the exosome is derived. Empty MHC molecules on exosomes may also be loaded with peptides afterwards.</p>

Title: Cell derived antigen presenting vesicles.

The invention relates to the field of immunology, especially the cellular responses of the immune system, more in particular to the induction of said responses by peptides presented in the context of major histocompatibility complexes I and/or II.

It is known that antigen presenting cells take up antigens through endocytosis, whereafter these antigens are cleaved into peptides which are presented at the surface of said antigen presenting cells in the context of a major histocompatibility complex. By this presentation on the surface the peptides derived from the original antigen can be recognized by for instance helper T-lymphocytes, further activating the cellular immune response.

Thus Helper T-lymphocytes recognize exogenous antigens bound to major histocompatibility complex (MHC) class II molecules expressed by a variety of antigen presenting cells (APCs) such as B-lymphocytes, macrophages and dendritic cells (1). Compelling evidence indicates that newly synthesized α and β subunits of MHC class II in association with the invariant chain (I-chain) are transported to intracellular compartments before reaching the plasma membrane (2,3). In these compartments the I-chain is degraded and MHC class II are potentially free to bind antigenic peptides arising from the degradation of antigens internalized by the APC (1, 4). We and others have shown that most of the intracellular MHC class II molecules reside in a lysosome-like, MHC-class II-enriched compartment (MIIC) which contains characteristic membrane vesicles and concentrically arranged membrane sheets (5, 6, 7, 8, 9, 10). MIICs and the related CIIVs (11), likely represent the meeting point between MHC class II and antigenic peptides (8,12). Once loaded with peptide, MHC class II molecules are transferred to the cell surface via an unknown pathway for presentation to T-lymphocytes.

Electron microscopy of immunogold labeled ultra thin cryosections from several human B-lymphoblastoid cell lines revealed MIICs whose surrounding membrane was contiguous with the plasma membrane in an exocytotic fashion and showed

5 extracellular vesicles reminiscent of those present in non-fused MIICs (Figure 1A and B). Similar secretion of vesicles, termed exosomes, has been described for reticulocytes (13). Exosomes from B cells immunolabeled for the lysosomal membrane proteins LAMP1 (Figure 1 B) and CD63 (not shown) known to be

10 expressed in MIICs (5, 6). Both LAMP1 and CD63 were absent from the rest of the plasma membrane. Scarce labeling for MHC class II was associated with the limiting membrane of the fused MIICs but MHC class II was enriched in the externalized exosomes (Figure 1A and B). To test the release of MIIC

15 contents further, B cells were allowed to internalize 5 nm gold particles conjugated to Bovine Serum Albumin (BSAG), and were then washed and reincubated in the absence of BSAG. Exosomes associated with previously endocytosed BSAG began to appear in exocytotic profiles after 30 min of uptake (10 min

20 pulse and 20 min chase) (Figure 1B) and were abundant after 50 min (10 min pulse and 40 min chase) (Figure 1A). We conclude that multivesicular MIICs of human B-cell lines can fuse with the plasma membrane thereby releasing MHC class II-rich exosomes into the extracellular milieu.

25 For a further characterization, exosomes were isolated from the culture media of the human B cell line RN by differential centrifugation (Figure 2). Pelleted membranes were analyzed by DS-PAGE and Western blotting. After removal of cells, the majority of MHC class II-containing membranes

30 sediment at 70.000 g (Figure 2 A, lane 6). The 70.000 g pellets were composed of a homogeneous population of vesicles labeled for MHC class II (Figure 2 B). The vesicles were morphologically similar to those present in MIICs and in exocytotic profiles of sectioned cells (Figures 1 A and B):

35 their size ranged from 60 to 80 nm. To obtain biochemical evidence that the secreted MHC class II is membrane bound, 70.000 g pellets were fractionated by floatation in linear

sucrose gradients (14). Western blot analysis of the non-boiled and non-reduced gradient fractions showed that MHC class II molecules floated to an equilibrium density of 1.13 g/ml, confirming their association with membrane vesicles (Fig. A). MHC class II molecules recovered from the gradient fractions were predominantly in the SDS-stable, compact form indicating their stabilization by bound peptides (15). Together, these results show that the secreted MHC class II is associated with membrane vesicles and has bound peptides. To determine the kinetics and the extent to which newly synthesized MHC class II molecules are released into the medium, RN cells were metabolically pulse-labeled for 45 min. with [³⁵S]-methionine and chased for up to 24 hours in the absence of label (16). After pulse-labeling MHC class II was immunoprecipitated as SDS-unstable α - β -1-chains complexes (Fig.3 B, lane 0). At 6 hours of chase part of MHC class II molecules were converted to SDS-stable, α - β -peptide complexes consistent with the kinetics reported for other human B cell lines (2, 17). Recovery of [³⁵S]-compact MHC class II from pelleted exosomes started at 12 hours and amounted 10 + 4% (n=5) of the total newly synthesized MHC class II after 24 hours of chase. The relatively slow rate by which newly synthesized MHC class II was secreted into the medium suggests that insertion from the limiting membrane of MIICs into the plasma membrane during exocytosis is probably not the only pathway by which MHC class II molecules are delivered to the cell surface. To test the possibility that the vesicles recovered from the medium represented shed plasma membrane fragments or cell debris instead of exosomes, cells and exosome preparations were biotinilated and the patterns of the biotinilated proteins were studied by Western blotting with ¹²⁵I-Streptavidin (18). Figure 3 C reveals differential patterns of biotinilated proteins in exosomes and plasma membranes. Whereas plasma membranes show a broad spectrum of biotinilated proteins (Figure 3C, lane 2), two proteins are enriched in exosomes (Figure 3C, lanes 3 and 4). Immunoprecipitation of the biotinilated exosomal proteins with

a monoclonal anti-class II antibody (19) identified these proteins as MHC class II (α and β subunits (Figure 3C, lane 1). Furthermore, the exosomes contain two minor bands at higher molecular weight which are not clearly detected in plasma membranes (Figure 3C, lanes 3 and 4). These proteins were also immunoprecipitated with the anti-class II antibody (Figure 3C, lane 1). To test the unlikely possibility that plasma membrane fragments eventually present in the 70.000 g pellets contributed to the enrichment of MHC class II in exosomes, biotinilated cells were homogenized and the homogenates were processed as the cell culture supernatants (18). Very low amount of membranes are pelleted at 70.000 g and these show a pattern of biotinilated proteins matching that of total plasma membrane, as expected (Figure 3C, lane 5). When the cells were metabolically labeled with [35 S]-methionine for 45 min. and chased for up to 24 hours (16), the [35 S]-Transferrin receptor (TfR) ([35 S]-TfR) did not appear in exosomes at any chase time (data not shown). TfR is present at the plasma membrane of B cells but is absent from MIIC (8, 10). Together, these observations emphasize that exosomes are not derived from shed plasma membranes but represent an unique population of MHC class II- enriched membrane vesicles.

Since the luminal domain of MHC class II molecules is exposed at the outside of exosomes (20), exosomes may be able to present antigens to T cells. To test this hypothesis, isolated exosomes were allowed to bind peptide 418-427 from the model antigen HSP 65 of Mycobacterium Leprae. The exosome preparations were then added to the T cell clone 2F10 which recognizes this peptide in the context of HLADR15 (21). In a parallel experiment, RN cells were allowed to endocytose HSP65 protein continuously for 24 hrs, washed, and incubated in the absence of antigen for another 24 hrs (22). Both, exosomes incubated with antigenic peptide (Figures 4 A and C) and exosomes derived from cells that were pre-incubated with antigen (Figures 4 B and D) were able to induce a specific T cell response (23). A half maximal response was obtained with an amount of exosomes secreted by 3×10^5 RN cells in 24 hours

(Fig.4 D). In comparison 2×10^4 intact RN cells were necessary to achieve the half maximal response (Fig.4 B, 24). The responses observed were DR restricted. Anti-HLA-DR antibody blocked T cell proliferation completely, whereas antiHLA-DP was ineffective (Figs 4 B and D). From these data we conclude that culture media of B cells provide for a source of MIIC-derived microvesicles (exosomes) that can induce T cell responses by themselves (25).

Exocytosis of MIIC vesicles by B-lymphocytes is reminiscent of the exocytosis of the vesicles contained in the cytolytic granules of cytotoxic T-lymphocytes (CTLs) (26). Both MIICs and cytolytic granules have lysosomal characteristics and contain internal membranes. The internal vesicles of cytolytic granules are exocytosed by the CTLs upon CTL-target cell interaction and presumably have a role in the killing of target cells (26). Whether B-cell exosomes also have an extracellular role *in vivo* remains to be established. It has been suggested that follicular dendritic cells acquire MHC class II molecules released from surrounding B cells by an unknown mechanism (27). It is worth studying the possibility that exosomes serve as carriers of MHC class II-peptide complexes between different cells of the immune system. Whether physiological APCs like dendritic cells and macrophages generate exosomes has to be studied (28). However, secretion of lysosomal contents by macrophages has been documented and macrophage tubular lysosomes are rich in MHC class II and contain membrane vesicles (29). It can be speculated that *in vivo*, exosomes may function as transport vehicles for MHC class II-peptide complexes responsible for maintenance of long term T cell memory or T cell tolerance. Finally, since exosomes can easily be obtained and are capable of presenting antigens specifically and efficiently, it is worth exploring their usefulness as biological vehicles in immunotherapy.

The invention therefore provides an antigen presenting vesicle free from its natural surroundings obtainable from

antigen presenting cells, such as B-cells, macrophages or dendritic cells, especially Langerhans cells of the epidermis.

These vesicles preferably will contain major histocompatiblility complex (MHC) I and/or II, most preferably
5 loaded with a peptide derived from or corresponding to an antigen which can be processed by antigen presenting cells.

It has been tried before to produce similar vesicles synthetically, for instance in the form of liposomes, but these attempts have sofar not been successful. Now that we
10 have surprisingly found that there are counterparts of said liposomes in nature, these counterparts can of course be used in any intended application of said liposomes.

The major advantage of the vesicles according to the invention is of course that they will automatically comprise
15 all the necessary elements for antigen presentation. Further analysis of the vesicles, once discovered will therefore result in a better understanding of which elements are essential for said presentation on said vesicles. It will then of course be possible to arrive at vesicles according to the
20 invention in other ways then by isolation from cells. The invention therefor does encompass all antigen presenting vesicles which comprise the essential elements for presenting such antigens, regardless of the way they are produced or obtained.

25 One may for instance think of synthetically prepared liposomes, provided with at least biologically active parts of (recombinant) MHC I or II, optionally provided with processing agents for antigens to be presented in the context of said MHC. Of course cells which produce these vesicles can also be
30 provided with recombinant MHC I or II encoding genes, so that the desired MHC's will be present on the eventually resulting vesicles, etc.

Although vesicles which present peptides in the context of MHC I or II are preferred, it is also very useful to
35 produce vesicles which do have the MHC's on their surface, but without a peptide being present therein. These vesicles can

then be loaded with desired peptides having the right binding
motiv to fit in the respective MHC.

The first and perhaps foremost use of these vesicles that
comes to mind is of course mimicking their role in nature,
5 which is the presentation of peptides as antigens, for the
stimulation of for instance T-cells. Thus the vesicles
according to the invention can be very suitably used in for
instance vaccines. These vaccines can be designed to elicit an
immune response against any proteinaceous substance which has
10 peptide antigens that can be presented in the context of MHC.

The vaccines may of course comprise suitable adjuvants,
if necessary, carriers, if necessary, excipients for
administration, etc.

The vaccines can be used in the treatment or prophylaxis
15 of many disorders, such as infections, immune disorders,
malignancies, etc.

Very important applications will of course be the
treatment or prophylaxis of AIDS, eliciting immuneresponses
agains tumours and the like.

20 Another important application of the vesicles according
to the invention is that they may be used to induce tolerance
to certain antigens, for instance by giving large doses of the
vesicles orally.

Based on the description of the invention and
25 specifically referring to the following experimental part
illustrating the invention the person skilled in the art will
be able to find further uses of the vesicles according to the
invention without departing from the spirit of the invention.

Legends to Figures:

Figure 1:

MIICs are exocytotic compartments. T2-DR3 cells were
5 incubated in the presence of 5 nm BSAG for 10 min., washed,
chased for 40 min. and processed for cryoultramicrotomy as
described (30). Ultrathin cryosections were immunolabeled with
a rabbit polyclonal anti-class II antibody (5) and antibody
binding sites were visualized with protein A conjugated to
10 gold (PAG with sizes in nm indicated on the figures). MHC
class II labeling is present at the limiting membrane of the
exocytotic profile and on the exosomes. The profile also
contains abundant re-externalized BSAG particles. PM: plasma
membrane. B, RN cells were pulsed with BSAG for 10 min. and
15 chased for 20 min. Ultrathin cryosections were double-
immunolabeled with anti-class II antibody and with a
monoclonal anti-LAMP1 antibody (31) as indicated. One of two
neighboring profiles is shown, exocytotic profile containing
BSAG and numerous exosomes labeled for MHC class II and
20 LAMP1. Bars, 0.1 μ m.

Figure 2:

Isolation of exosomes from cell culture media. A, RN
cells were washed by centrifugation and re-cultured in fresh
25 medium for 2 days. Cell culture media (35 ml) containing 2-5
 $\times 10^8$ RN cells were centrifuged twice for 10 min. at 300 g
(lane 1, first run; lane 2, second run). Lane 1 contains
material from 0.6×10^6 cells. Membranes in the culture medium
from $2-5 \times 10^8$ cells were pelleted by sequential
30 centrifugation steps: twice at 1200 g (lane 3 and 4), and once
at 10.000 g (lane 5), 70.000 g (lane 6) and 100.000 g (lane
7). The pellets were solubilized at 100°C under reducing
conditions and analyzed by Western blotting using [125 I]-
protein A. Per lane, samples equivalent to 1×10^6 cells were
35 loaded. MHC class II α and β chains were recovered mainly from
the cells (lane 1) and from the 70.000 g pellet (lane 6). B,
whole mount electron microscopy of the 70.000 g pellet

immunogold labeled for MHC class II. The 70.000 g pellet was resuspended in RPMI medium, adsorbed to Formvar-carbon coated EM grids, fixed with 0.5 % glutaraldehyde in 0.1 M phosphate buffer, immunolabeled with rabbit polyclonal anti-class II antibody and 10 nm PAG and stained using the method described for ultra-thin cryosections (30). The pellet is composed of 60-80 nm vesicles showing abundant MHC class II labeling. Bar, 0.2 μ m

Figure 3:

A, MHC class II present in the media are membrane bound. Membranes pelleted from culture media at 70.000g after differential ultracentrifugation were fractionated by floatation on sucrose gradients, and the non-boiled and non-reduced fractions analyzed by SDS-PAGE and Western blotting with the rabbit polyclonal anticlass II antibody (17). MHC class II molecules were recovered in fractions 5 to 12 corresponding to densities of 1.22-1.10 g/ml. The majority of MHC class II was in the SDS-stable compact form with a MW of 56-60 kD ($\alpha\beta$).

B, Release of newly synthesized MHC class II molecules. RN cells were pulse-labeled with [35 S] methionine for 45 min. (lane 0) followed by chases in the absence of label for 6, 12 and 24 hours. MHC class II molecules were immunoprecipitated from lysates of the cells and pelleted exosomes with the monoclonal DA6.231 anti-class II antibody (18). Immunoprecipitated MHC class II molecules were dissociated from the sepharose beads at non-reducing conditions at room temperature and analyzed by SDS-PAGE and fluorography. After pulse-labeling (0), MHC class II immunoprecipitated from the cells as SDS-unstable complex of α - β -invariant chain. SDS-stable α - β dimers were recovered from the cells after 6 hours of chase and the signal increased thereafter. In the exosomes pellets SDS-stable $\alpha\beta$ dimers started to appear at 12 hours. C, Exosomes and plasma membrane display different patterns of biotinilated proteins (18). In plasma membranes (lane 2) and experimentally produced remnants of plasma membranes (18) many

biotinilated proteins are detected with ^{125}I Streptavidin (lane 5). In exosomes (lanes 3 and 4, show increasing concentrations of exosomes, respectively) two major proteins with a MW of 60-70 kD are detected. Lane 1 shows the immunoprecipitation of biotinilated class II α and β chains from exosomes lysates. In these assay the higher electrophoretical mobility of α and β chains is due to their efficient binding to biotin. Two minor bands at a MW of 200-300 kD are detected in exosomes (lanes 1, 3 and 4, arrows) and are absent from the plasma membrane.

10

Figure 4:

Presentation of HSP 65 antigen by HLA-DR15 positive RN B cells and exosomes to the CD4^+ T cell clone 2F10 (22). Proliferative responses to naive cells (A), to cells pre-incubated with antigen (B), to exosomes derived from naive cells (C) and to exosomes derived from cells pre-incubated with antigen (D). The closed symbols show proliferation measurements after addition of HSP 65 derived peptide (418-427), the open symbols where peptide was not added. HLA-class II restriction was determined by adding 10 $\mu\text{g}/\text{ml}$ anti-DR antibody (triangles), anti-DP (circles), or no antibody (squares). The exosomes at the highest concentration were derived from media of 1.6×10^6 cells. All assays were performed in triplicate and results are expressed in cpm [^3H]-thymidine incorporated into T cells. The SEM for triplicate cpm measurements was less then 10%. Results shown form a representative example of experiments performed in duplo.

- 20 21. T. H. M. Ottenhof, et al., *Nature (Lond.)* **319**, 66-68 (1986).
- 25 J. B. A. G. Haanen, et al., *J. Exp. Med.* **174**, 583-592 (1991).
22. The EBV-B cell lines RN (HLA-DR 15+) and JY (HLA-DR15-) were incubated in the presence or absence of purified HSP 65 protein from *Mycobacterium Leprae* (50 $\mu\text{g}/\text{ml}$) [J.E.R. Thole, et al., *Microbial Pathogenesis* **4**, 71-83 (1988)]
- 30 for 4 hr in 10 ml serum free RPMI at 2×10^6 cells /ml, followed by the addition of 30 ml RPMI supplemented with 10% fetal calf serum (FCS) for 20 hr at 37°C. The cells were then washed to remove free antigen and incubated further for 24 hrs in RPMI/10% FCS medium at 37°C.
- 35 Exosomes were prepared by differential centrifugation (Figure 2) and the efficiency of HSP 65 antigen presentation was measured by culturing 10.000 cells of

- the T cell clone 2F10 with irradiated (6.000 rad) EBV cells. B cells or exosomes resuspended in 100 µl IMDM /10% pooled human serum were added to the T cell clone (50 µl IMDM /10% pooled human serum per well) in 96 well flatbottom microtitre plates (Costar, The Netherlands) for 4 days at 37°C, 5% CO₂ in humidified air. When indicated, 5 µg/ml of HLA-DR15 restricted epitope of HSP65 (peptide 418-427) was added to the exosomes. Sixteen hours before termination 0.5 µCi of [³H]-thymidine was added to the wells. The cells were then harvested on glass fiber filters using an automatic cell harvester and the [³H]-thymidine incorporation into cell DNA was determined by liquid scintillation counting. The results are expressed as the mean of triplicate measurements).
23. As a control, exosomes were prepared from culture media of an equivalent amount of DR15-negative JY cells that have been incubated or not with antigen. JY cells secreted an equivalent amount of exosomes but these were ineffective in stimulating T cell proliferation.
24. From these data exosomes appear to be 16 times less efficient in antigen presentation. However, in antigen presentation assays contact between B and T cells may be more efficient due to sedimentation of cells.
25. Exosomes isolated from the culture medium of the murine B cell line TA3 (I-E^k) incubated in the presence a RNase-derived peptide (aa 90-105) were also capable of stimulating IL2 secretion by WA.23 cells.
26. P. Peters, H. J. Geuze, H. A. van der Donk, J. Borst, *Immunol. Today* 11, 28-32 (1990)
P. J. Peters, et al., *J. Exp. Med.* 173, 1099-1109 (1991 b).
27. D. Gray, M. Kosco, B. Stockinger, *Int. Immunol.* 3, 141-148 (1991).
28. A number of studies documented the presence of intact MHC class II molecules in 100.000 g fractions from B cell culture media and their association of with membrane

- lipids [S. G. Emerson, R. E. Cone, *J. Immunol.* **122**, 892-899 (1979);
- D. H. Sachs, P. Kiskiss, K. J. Kim, *J. Immunol.* **124**, 2130-2136 (1980); S. G. Emerson, R. E. Cone, *J. Immunol.* **127**, 482-486 (1981)]. Our present observations shed new light on these data and suggest that the released MHC class II molecules were likely derived from secreted exosomes.

PCT 0493

CLAIMS

1. Antigen presenting vesicle free from its natural surroundings obtainable from antigen presenting cells.
2. Vesicle according to claim 1, comprising at least a biologically active part of an major histocompatiblity comlex
- 5 class I or class II or a derivative thereof.
3. Vesicle according to claim 2 which additionally comprises at least partly processed antigens.
4. Vesicle according to claim 3 wherein processed antigen is present in the context of major histocompatibility complex 1
- 10 or 2.
5. Vesicle according to anyone of the foregoing claims for use as a therapeutical.
6. Vesicle according to anyone of the foregoing claims which is derived from a B-lymphocyte, a macrophage or a
- 15 dendritic cell.
7. Vaccine composition comprising a vesicle according to anyone of claims 1-4 together with a usual adjuvans or carrier.
8. Use of a vesicle according to anyone of claims 1-4 in the
- 20 preparation of a medicament for the treatment or prophylaxis of immune disorders or infections.
9. Method for the preparation of a vesicle according to anyone of claims 1-4, comprising the steps of differential centrifugation of membrane fractions of cell culture
- 25 supernatants or lysates and recovery of the fraction containing said vesicles.
10. Method for stimulating a T cell response comprising the step of contacting T cells with a vesicle according to claim 3 or 4.

INTERNATIONAL SEARCH REPORT

International Application No

PC1/NL 96/00317

A. CLASSIFICATION OF SUBJECT MATTER
IPC 6 A61K39/385

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
IPC 6 A61K

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	NATURE, vol. 315, 1985, LONDON GB, pages 327-329, XP002016307 WALDEN P. ET AL: "Induction of regulatory T-lymphocyte responses by liposomes carrying major histocompatibility complex molecules and foreign antigen" see the whole document ---	1-8,10
X	JOURNAL OF IMMUNOLOGY, vol. 151, no. 8, 1993, BALTIMORE US, pages 3988-3998, XP002016308 HARDING C.V. ET AL: "Immunogenic peptides bind to class II MHC molecules in an early lysosomal compartment" see the whole document ---	1-10
	-/--	

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

* Special categories of cited documents:

- *A* document defining the general state of the art which is not considered to be of particular relevance
- *E* earlier document but published on or after the international filing date
- *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- *O* document referring to an oral disclosure, use, exhibition or other means
- *P* document published prior to the international filing date but later than the priority date claimed

T later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

X document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

Y document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

G document member of the same patent family

Date of the actual completion of the international search

18 October 1996

Date of mailing of the international search report

INTERNATIONAL SEARCH REPORT

International application No.

PCT/NL 96/ 00317

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
Please see Further Information sheet enclosed.
2. ☐ Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/210

Remark : Although claim 10 (partially when the method is carried out in vivo) is directed to a method of treatment of the human/animal body the search has been carried out and based on the alleged effects of the compound/composition.

BEST AVAILABLE IMAGES

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- ☐ BLACK BORDERS
- ☐ IMAGE CUT OFF AT TOP, BOTTOM OR SIDES
- ☐ FADED TEXT OR DRAWING
- ☒ BLURRED OR ILLEGIBLE TEXT OR DRAWING
- ☐ SKEWED/SLANTED IMAGES
- ☐ COLOR OR BLACK AND WHITE PHOTOGRAPHS
- ☐ GRAY SCALE DOCUMENTS
- ☐ LINES OR MARKS ON ORIGINAL DOCUMENT
- ☐ REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY
- ☐ OTHER: _____

IMAGES ARE BEST AVAILABLE COPY.

As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.
